

CROP DATA SHEET · ORCHARD CROP

# Apple

Stronger, more resilient trees and better fruit, on less synthetic nitrogen.

## +8-10%

TYPICAL YIELD GAIN

CROSS-CROP AVERAGE · UP TO ~14% UNDER STRESS

### +8-10%

#### YIELD

Typical gain vs. untreated; greater as heat or drought stress rises.

### 30-50%

#### LESS NITROGEN

Matched full-rate yield at reduced N (Harman 2011).

### Improved

#### ROOTS & VIGOR

Stronger root development and establishment across trials.

#### WHEN TO APPLY

Apply by **seed treatment**, **in-furrow** at planting, or as a **foliar pass**. Earlier is better, but a foliar pass well into the **vegetative stage** still delivers a real benefit — it is never too late to start.

#### HOW THE PROGRAM WORKS

##### Holds up under stress

Living inputs help the plant manage heat, drought and salinity, so more of the season goes into the crop.

##### More growth

Symbiotic signalling lifts growth rate and nutrient-use efficiency across the canopy.

##### Healthier root zone

A richer root environment frees up soil nutrients, so the crop leans less on synthetic NPK.

## FIELD-TRIAL EVIDENCE

Apple has not yet been through a Symm-specific field trial, so the figures below are the general cross-crop results from independent peer-reviewed research. They point to where the program helps most in apple: holding fruit set and quality through heat and drought, supporting young-tree establishment, and cutting nitrogen cost.

| YEAR | REGION                           | APPLICATION          | RESULT                                   |
|------|----------------------------------|----------------------|------------------------------------------|
| —    | Peer-reviewed (Cornell / Harman) | Trichoderma research | <b>+8-10% yield, improved roots</b>      |
| 2011 | Peer-reviewed · Harman           | Nitrogen study       | <b>30-50% N reduction, no yield loss</b> |

General cross-crop figures from independent peer-reviewed research, shown as ranges; not apple-specific trial results and never a guarantee for a given field. Yield gain is typically +8 to 10%, up to ~14% under abiotic stress.
