

CROP DATA SHEET · CEREAL · ROW CROP

Barley

Stronger stands and steady yield through a dry, hot finish.

+8-10%

TYPICAL YIELD GAIN

CROSS-CROP AVERAGE · UP TO ~14% UNDER STRESS

+8-10%

YIELD

Typical gain vs. untreated; greater as heat or drought stress rises.

30-50%

LESS NITROGEN

Matched full-rate yield at reduced N (Harman 2011).

Improved

ROOTS & VIGOR

Stronger root development and establishment across trials.

WHEN TO APPLY

Apply by **seed treatment**, **in-furrow** at planting, or as a **foliar pass**. Earlier is better, but a foliar pass well into the **vegetative stage** still delivers a real benefit — it is never too late to start.

HOW THE PROGRAM WORKS

Holds up under stress

Living inputs help the plant manage heat, drought and salinity, so more of the season goes into the crop.

More growth

Symbiotic signalling lifts growth rate and nutrient-use efficiency across the canopy.

Healthier root zone

A richer root environment frees up soil nutrients, so the crop leans less on synthetic NPK.

FIELD-TRIAL EVIDENCE

Barley has not been through a Symm-specific trial; the figures below are the general cross-crop results from independent peer-reviewed research, pointing to yield through a dry, hot finish and lower nitrogen cost.

YEAR	REGION	APPLICATION	RESULT
—	Peer-reviewed (Cornell / Harman)	Trichoderma research	+8-10% yield, improved roots
2011	Peer-reviewed · Harman	Nitrogen study	30-50% N reduction, no yield loss

General cross-crop figures from independent peer-reviewed research, shown as ranges; not barley-specific trial results and never a guarantee for a given field. Yield gain is typically +8 to 10%, up to ~14% under abiotic stress.
